

Table 1. Results of the additive and multiplicative diversity partitioning of gobiid fishes.

	Spatial level	Observed values	Expected values	
			Mean	Intervals
Additive partition				
	$\bar{\alpha}$	7.4	<i>nd</i>	<i>nd</i>
	β_{add1}	13.6	<i>nd</i>	<i>nd</i>
	β_{add2}	13.5*	5.68	2.57-9.5
	β_{add3}	27.5*	18.32	13.75-27.5
	β_{add4}	24	31.46	24-46.5
Multiplicative partition				
	$\bar{\alpha}$	7.4	<i>nd</i>	<i>nd</i>
	B_{mult1}	2.84	<i>nd</i>	<i>nd</i>
	B_{mult2}	1.64*	1.2	1.08-1.38
	B_{mult3}	1.8*	1.43	1.28-1.8
	B_{mult4}	1.39	1.56	1.39-1.9

Expected interval is the minimum and maximum values produced by an expected distribution of the diversity components from which *p*-values are obtained under null models built by 10,000 randomizations. * = statistical significance ($p \leq 0.001$). *nd*= no data. Sample-based randomization cannot be applied to the lowest level of analysis (level 1); thus, no statistical null distribution was produced to this level.
